# 1 Basic definitions

## 1.1 Assigning field extensions a group

### Definition 1.1: Automorphism group

Let  $K/F$  be a field extension.

$$\text{Aut}(K/F) := \{\sigma : K \rightarrow K \mid \sigma|_F = \text{id}_F\}$$

### Theorem 1.1: Automorphism group permutes the roots

Let  $m_{\alpha,F}(x)$  be the minimal polynomial of  $\alpha$ .  $\forall \sigma \in \text{Gal}(K/F)$ ,  $m_{\alpha,F}(\sigma\alpha) = 0$ .  
In other words,  $\text{Aut}(K/F)$  permutes the roots of  $m_{\alpha,F}$ .

This theorem gives us a tool to compute the automorphism groups concretely.

**Example** (1)  $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$

(2)  $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ ,

(3)  $\mathbb{R}/\mathbb{Q}$

## 1.2 Assigning groups a field

Consider a subgroup  $H \leq \text{Aut}(K) = \text{Aut}(K/\{0\})$ . Let  $F$  be the collection of elements of  $K$  fixed by  $H$ , i.e.

$$F = \{k \in K : \forall \sigma \in H, \sigma(k) = k\}$$

Such a collection is called fixed field. Then, we would like to say:

(1) This collection  $F$  is indeed a field.

(2) We will see no matter  $H$  is the subgroup of  $\text{Aut}(K)$  (it could be just a set),  $F$  is a field. But only when  $H$  is the subgroup of  $\text{Aut}(K)$ .  $F$  is called a fixed field.

### Definition 1.2: Fixed field

### Theorem 1.2: Fixed field is a field

## 1.3 Galois extension

### Definition 1.3: Galois extension

### Theorem 1.3: Characterisation theorem for Galois extension

Let  $K/F$  be a field extension.  $K/F$  is Galois  $\Leftrightarrow K$  is the splitting field of **some** separable polynomial over  $F$

Upshot: Criteria for an extension to be Galois:

(1)  $|\text{Aut}(K/F)| = [K : F]$

(2)  $K/F$  is a ?? finite extension and  $f \in F[x]$  is a separable polynomial, then  $K$  is the splitting field of  $f$ .

(3) definition

### 1.3.1 Calculating some Galois groups

(1)

(2) Finite extension of a finite field  $\mathbb{F}_{p^n}/\mathbb{F}_p$ : This extension is separable since  $f(x) = x^{p^n} - x$  is separable and  $\mathbb{F}_{p^n}$

is the splitting field of  $f$  over  $\mathbb{F}_p$ .

$$\text{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) \cong \langle \sigma_p \rangle \cong \mathbb{Z}/n\mathbb{Z}$$

(3) Finite extension of  $\mathbb{K}/\mathbb{F}_p$ : Let  $\mathbb{K}$  be a finite extension of the finite field  $\mathbb{F}_q$ ,  $q = p^a$ . Then,  $\mathbb{K}/\mathbb{F}_q$  is a Galois extension and  $\text{Gal}(\mathbb{K}/\mathbb{F}_q)$  is a cyclic group of order  $[\mathbb{K} : \mathbb{F}_q]$  generated by the Frobenius element  ${}_q : \mathbb{K} \rightarrow \mathbb{K}, x \mapsto x^q$ , i.e.  $\text{Gal}(\mathbb{K}/\mathbb{F}_q) = \langle {}_q \rangle$ .

**Proof:** First, this extension is Galois.

Then, the Frobenius element belongs to the Galois group  $\text{Gal}(\mathbb{K}/\mathbb{F}_q)$ .  ${}_q$  is an automorphism.  ${}_q$  fixes every element in  $\mathbb{F}_q$ . Since every element in  $\mathbb{F}_q^\times$  has order  $q - 1$ . So,  $\forall x \in \mathbb{F}_q, {}_q(x) = x^q = x$ . Thus,  ${}_q \in \text{Gal}(\mathbb{K}/\mathbb{F}_q)$ .

There is nothing more than  $\langle {}_q \rangle$  in  $\text{Gal}(\mathbb{K}/\mathbb{F}_q)$ . ?? gives that  $\mathbb{K}^\times$  is cyclic. So,  $\exists y \in \mathbb{K}^\times$  with order  $q^n$ , i.e.  $\forall 1 \leq l \leq q^n - 1, y^l \neq y$ . Apply  ${}_q$   $k$  times:  ${}_{q^k}(y) = y^{q^k}$ .  $\forall 1 \leq k \leq n - 1, {}_{q^k}(y) \neq 1$ . But for  $n$ ,  ${}_{q^n}(y) = y$ . This shows that  ${}_q$  generates a cyclic subgroup of order  $n$  in  $\text{Gal}(\mathbb{K}/\mathbb{F}_q)$ . But,  $|\text{Gal}(\mathbb{K}/\mathbb{F}_q)| = [\mathbb{K} : \mathbb{F}_q] = n$ . So, the only possibility is  $\text{Gal}(\mathbb{K}/\mathbb{F}_q) = \langle {}_q \rangle$ .  $\square$

(4) Finite cyclotomic extension over  $\mathbb{Q}$

## 2 Fundamental theorem of Galois theory

### Theorem 2.1: Artin's theorem[Connnd]

Let  $E$  be a field and  $H \leq \text{Aut}(E)$  be a finite subgroup.  $[E : E^H] < +\infty$ . Then  $E/E^H$  is a Galois extension with  $\text{Gal}(E/E^H) = H$ .

Moreover, this also implies that  $[E : E^H] = |\text{Gal}(E/E^H)| = |H|$ .

**Proof:** • First we show that the field extension  $E/E^H$  is separable and every element  $\alpha \in E$  has bounded degree. Suppose that  $\{\sigma_1(\alpha), \dots, \sigma_k(\alpha)\}$  are distinct elements of  $\{\sigma(\alpha) : \sigma \in H\}$  into . Consider the polynomial  $h_\alpha(x) = \prod_{i=1}^k (x - \sigma_i(\alpha))$ . Definitely,  $\alpha$  is a root of  $h_\alpha(x)$  and  $h_\alpha(x) \in E^H[x]$  state the reason. Because every  $\alpha \in E$  is algebraic and separable over  $E^H$ . So,  $E/E^H$  is an algebraic extension, and each  $\alpha$  has a degree  $\leq |H|$  over  $E^H$ . why extension finite

Hence, by the primitive element theorem,  $\exists \alpha \in E$ , such that  $E = E^H(\alpha)$ . So there is an element  $\beta$ , such that  $[E^H(\beta) : E^H]$  is maximal.

• Next, we claim that  $E = E^H(\beta)$  <sup>1</sup>:  $\forall \gamma \in E, E^H(\beta) \subseteq E^H(\beta, \gamma) \subseteq E$ . Since  $E^H(\beta, \gamma)/E^H(\beta)$  is a finite separable extension, the primitive element theorem predicts again that  $\exists \delta \in E, E^H(\beta, \gamma) = E^H(\delta)$ . Then,  $[E^H(\beta) : E^H] \leq [E^H(\beta, \gamma) : E^H] = [E^H(\gamma) : E^H]$ . But as we assumed,  $[E^H(\beta) : E^H]$  is the largest, so  $[E^H(\beta) : E^H] = [E^H(\gamma) : E^H]$ , meaning  $E^H(\beta) = E^H(\beta, \gamma)$  and then  $\gamma \in E^H(\beta)$ . Since this is for arbitrary  $\gamma \in E$ , this implies that  $E \subseteq E^H(\beta)$ . Hence,  $E = E^H(\beta)$ .

• Then, we are going to use the fact that  $[E : E^H] < \infty$

$$[E : E^H] = [E^H(\alpha) : E^H] = \deg m_{\alpha, E^H}(x) \leq \deg h_\alpha(x) \leq |H|$$

$h_\alpha(x)$  splits over  $E$  splitting fields?, so  $E/E^H$  is a Galois extension.  $\forall \sigma \in H, \sigma|_{E^H} = \text{id}_{E^H}$ , hence  $H \leq \text{Gal}(E/E^H)$ . So, we get the equality  $|H| = |\text{Gal}(E/E^H)|$  and then  $H = \text{Gal}(E/E^H)$ .  $\square$

<sup>1</sup>This  $\beta$  may not be agree with the  $\alpha$  making  $E^H(\alpha) = E$ , so we cannot directly say that  $E^H(\beta) = E$

## Theorem 2.2: Fundamental theorem of Galois theory

Let  $K/F$  be a Galois extension. There is a bijection:

$$\begin{aligned} \{\text{intermediate field } E \text{ between } K \text{ and } F : K/E/F\} &\longleftrightarrow \{\text{intermediate group } H : \{1\} \leq H \leq \text{Gal}(K/F)\} \\ f : E &\mapsto \text{Gal}(K/E) \\ g : K^H &\leftrightarrow H \end{aligned}$$

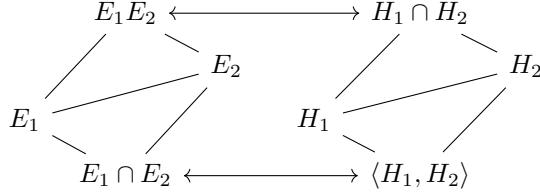

so that  $(g \circ f)(E) = K^{\text{Gal}(K/E)} = E$  and  $(f \circ g)(H) = \text{Gal}(K/K^H) = H$ .  $f, g$  are inverse to each other. Moreover, let intermediate fields  $E_1, E_2$  correspond to two intermediate groups  $H_1, H_2$ , respectively. This bijection has the following properties:

- (1) (inclusion-reversing)  $E_1 \subseteq E_2 \Leftrightarrow H_2 \leq H_1$ .
- (2)  $[E_2 : E_1] = [H_1 : H_2]$
- (3)  $E_2/E_1$  is a Galois extension  $\Leftrightarrow H_2 \trianglelefteq H_1$ . In this case,  $\text{Gal}(E_2/E_1) \cong H_1/H_2$
- (4)  $E_1 \cap E_2$  corresponds to the group  $\langle H_1, H_2 \rangle$ .  $H_1 \cap H_2$  corresponds to the composite field  $E_1 E_2$

**Remark** • There is a subtlety in the definition  $E \mapsto \text{Gal}(K/E)$ . Is the extension  $K/E$  a Galois extension for an arbitrary intermediate field  $E$  inside  $K/E/F$ ?

The answer is yes. For an arbitrary intermediate field  $E$ . We always have  $K/E$  is normal, but  $E/F$  not necessarily normal. Both  $K/E$  and  $E/F$  are spearable. Hence,  $K/E$  is always Galois for an intermediate field  $E$  between a Galois extension  $K/F$ .

• The last properties is illustrated as:

The lattice of subfields and the lattice of subgroups are dual—they are upside down to each other.

This correspondence can be reformulated in the language of category. Fix a Galois extension  $K/F$ . Let  $\mathbf{FldExt}_{K/F}$  be the category whose objects are all intermediate field extension of  $K$  and below  $L$ , and whose morphisms are inclusion maps. Then, let  $\mathbf{Gp}_{\text{Gal}(k/F)}$  be the category whose objects are subgroups of  $\text{Gal}(L/K)$  and whose morphisms are inclusion maps.

The correspondence is rephrased as a contravariant functor

$$\mathcal{G} : \mathbf{FldExt}_{K/F} \rightarrow \mathbf{Gp}_{\text{Gal}(K/F)}$$

such that  $\mathcal{G}(E) = \text{Gal}(K/E)$  and for any morphism  $\iota : E_1 \hookrightarrow E_2$ ,  $\mathcal{G}(\iota) = \text{Gal}(K/E_2) \hookrightarrow \text{Gal}(K/E_1)$ .

Conversely, given a Galois group  $G := \text{Gal}(K/F)$ , there is a contravariant functor

$$\mathcal{F} : \mathbf{Gp}_G \rightarrow \mathbf{FldExt}_{K/F}$$

such that  $\mathcal{F}(H) = K^H$  and for any morphism  $\iota : H_1 \hookrightarrow H_2$ ,  $\mathcal{F}(\iota) : K^{H_2} \hookrightarrow K^{H_1}$ .

From the statement of the theorem, define  $\epsilon : \mathcal{G} \circ \mathcal{F} \rightarrow \mathbb{1}_{\mathbf{Gp}_{\text{Gal}(K/F)}}$  to be identity on each subgroup  $H$ ,  $\epsilon$  is a natural isomorphism. Similarly, another natural isomorphism  $\eta : \mathbb{1}_{\mathbf{FldExt}_{K/F}} \rightarrow \mathcal{F} \circ \mathcal{G}$  can be given. So,  $\mathbf{FldExt}_{K/F}$  and  $\mathbf{Gp}_{\text{Gal}(K/F)}$  are equivalent as categories(more strictly, this is an isomorphism of categories).

**Proof:** • This map is well-defined. Given  $H \leq G$ , we have the unique fixed field  $K^H$ .  $\forall \sigma \in H \subseteq \text{Gal}(K/F)$ ,  $\sigma$  fixes all elements in  $F$ . Hence,  $F \subseteq K^H$ . Hence,  $g$  is injective.

For the other side, since  $K/F$  is Galois, so theorem 1.3 gives the existence of a polynomial  $f(x) \in F[x]$  such that  $K$  is the splitting field of  $f$  which is separable.  $f(x)$  can also be viewed as  $\in E[x]$ . By theorem 1.3 again,  $K/E$  is Galois. So,  $f$  is well-defined.  $\square$

**Example** (1) For finite fields  $\mathbb{F}_p, \mathbb{F}_{p^n}$ . Every subfield of  $\mathbb{F}_{p^n}$  is  $\mathbb{F}_{p^d}$  with  $d|n$ .

(2) For cyclotomic field extension  $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ , every intermediate field of this extension is  $\mathbb{Q}(\zeta_m)$  with  $m|n$ .

There is some subtlety on the choice of morphisms: given an injection of fields,  $\iota : E_1 \hookrightarrow E_2$ , why the correspondence(the functor  $\mathcal{G}$ ) takes this  $\iota$  to the inclusion? It seems that there are two choices of destinations: either

an inclusion, or a 'projection' map  $\text{Gal}(K/E_1) \rightarrow \text{Gal}(K/E_2)$ .

This does not generally hold because the projection map requires  $\text{Gal}(K/E_2)$  is isomorphic to a quotient group of  $\text{Gal}(K/E_1)$ , not only a subgroup of it.

But, this failure does not refute that the idea of 'projecting  $\text{Gal}(K/E_1)$  to something' is useless. This idea works after slightly modifying the condition: we should assume  $K/F$  is a normal extension.

## 2.1 Linear algebra under Galois theory

[DF03]

### Definition 2.1: Norm of Galois extensions

Let  $L/K/F$  be finite extensions with  $\alpha \in K$ ,  $K/F$  finite and  $L/F$  Galois. The **norm** of  $\alpha$  from  $K$  to  $F$ , denoted  $\text{Nm}_{K/F}(\alpha)$ ,

$$\text{Nm}_{K/F}(\alpha) := \prod_{\sigma \in \{K \hookrightarrow \bar{F}\}} \sigma(\alpha)$$

In particular, if  $K/F$  is Galois,  $\text{Nm}_{K/F}(\alpha) := \prod_{\sigma \in \text{Gal}(K/F)} \sigma(\alpha)$ .

**Remark** Notice that this definition works broadly. Even for the extension  $K/F$  that is not Galois.

### Theorem 2.3: Properties of norm

Let  $L/K/F$  be finite extensions with  $\alpha \in K$ ,  $K/F$  finite,  $L/F$  Galois.

- (1)  $\text{Nm}_{K/F} : K \rightarrow F$  is a multiplicative map.
- (2) Let  $K = F(\sqrt{D})$  be a quadratic extension. Then,  $\text{Nm}_{K/F}(a + b\sqrt{D}) = a^2 - Db^2$ .
- (3) Let  $m_\alpha(x) = x^d + a_{d-1}x^{d-1} + \cdots + a_1x + a_0 \in F[x]$  be the minimal polynomial for  $\alpha \in K$  over  $F$ . Let  $n := [K : F]$  and  $d|n$ , then  $\text{Nm}_{K/F}(\alpha) = (-1)^n a_0^{n/d}$ .

**Proof:** • First,  $\text{Nm}_{K/F}(\alpha) \in F$ , by showing it is fixed by any  $\tau \in \text{Gal}(K/F)$ .

Suppose that  $m_\alpha(x)$  has roots  $\alpha_1, \alpha_2, \dots, \alpha_n$ , then  $m_\alpha(x) = \prod_{i=1}^d (x - \alpha_i)$ . Expand it and compare the coefficients with the form  $x^d + a_{d-1}x^{d-1} + \cdots + a_1x + a_0$ .  $(-1)^d \alpha_0 \alpha_1 \cdots \alpha_d = a_0$ . Since Galois group permutes the roots of  $m_\alpha(x)$ , there are  $d$  distinct elements of  $m_\alpha(x)$ .  $\square$

### Definition 2.2: Trace of Galois extensions

Let  $L/K/F$  be finite extensions with  $\alpha \in K$ ,  $K/F$  finite and  $L/F$  Galois. The **trace** of  $\alpha$  from  $K$  to  $F$ , denoted  $\text{Tr}_{K/F}(\alpha)$ ,

$$\text{Tr}_{K/F}(\alpha) := \sum_{\sigma \in \{K \hookrightarrow \bar{F}\}} \sigma(\alpha)$$

### Theorem 2.4: Properties of trace

Let  $L/K/F$  be finite extensions with  $\alpha \in K$ ,  $K/F$  finite,  $L/F$  Galois.

- (1)  $\text{Tr}_{K/F} : K \rightarrow F$  is an additive map.
- (2) Let  $K = F(\sqrt{D})$  be a quadratic extension. Then,  $\text{Tr}_{K/F}(a + b\sqrt{D}) = a^2 - Db^2$ .
- (3) Let  $m_\alpha(x) = x^d + a_{d-1}x^{d-1} + \cdots + a_1x + a_0 \in F[x]$  be the minimal polynomial for  $\alpha \in K$  over  $F$ . Let  $n := [K : F]$  and  $d|n$ , then  $\text{Tr}_{K/F}(\alpha) = (-1)^1 \frac{n}{d} a_{n-1}$ .

**Proof:**

$\square$

## 2.2 An application: Hilbert's Theorem 90

# 3 Galois groups of some certain extensions

## 3.1 Finite field extensions

## 3.2 Composite and simple extensions

## 3.3 Cyclotomic and Abelian extensions over $\mathbb{Q}$

## 3.4 Kummer extension

## 3.5 Artin-Schreier extension

# 4 Galois group of polynomials

In section 1, by 1.1, since Galois group is the special case of automorphism groups, we know that for a polynomial  $f(x) \in F[x]$ ,  $\text{Gal}(f)$  permutes the roots of  $f$ . If  $f$  has degree  $n$ , the roots of  $f$  can be listed:  $\{\alpha_1, \dots, \alpha_n\}$  (counting multiplicity). So, the effect of  $\text{Gal}(f)$  on each  $\alpha_i$  is what some subgroup of  $S_n$  does for  $i$ . In this sense,  $\text{Gal}(f)$  can be thought of as a subgroup of  $S_n$

$$\text{Gal}(f) \hookrightarrow S_n$$

From another perspective, every finite group is asserted by Cayley's theorem to have a subgroup of  $S_N$  for some  $N$ . Seemingly, Cayley's theorem guarantees  $\text{Gal}(K/F) \hookrightarrow S_n$ . But this is not the case, because we do not know in priori the  $N$  in  $S_N$  given by Cayley is exactly the  $n$  as the amount of roots of  $f$ .

This embedding tells us something: If  $K$  is the splitting field of  $f(x) \in F[x]$  with  $\deg f(x) = n$  over  $F$ , then  $|\text{Gal}(K/F)| \leq |S_n| = n!$ . This is a group-theoretical way to explain why the degree of extension of a splitting field of  $f$  over  $F \leq n!$ .

If  $f(x) = f_1(x) \cdots f_k(x)$  can be written as a product of irreducible polynomials (each  $f_i(x)$  is irreducible). Then,  $\text{Gal}(f) \leq \text{Gal}(f_1) \times \cdots \times \text{Gal}(f_k)$

How does  $\text{Gal}(f)$  act on the roots of  $f$ ? (What properties does this action have?) First, this action is transitive.

## 4.1 Galois Groups as $S_n$ and $A_n$

### 4.1.1 Symmetric functions and $S_n$

#### Definition 4.1: Elementary symmetric polynomials

Consider the action of  $S_n \curvearrowright \{s_1, \dots, s_n\}$ , for each  $i$ ,  $s_i$  is invariant under  $\sigma \in S_n$ , i.e.  $s_{\sigma(i)} = s_i$ . Then, consider an action  $S_n \curvearrowright F(x_1, \dots, x_n)$ , by permuting the indexes. Then we have the general definition of symmetric polynomial

#### Definition 4.2: Symmetric polynomial

#### Theorem 4.1: Fundamental theorem of symmetric function

#### Definition 4.3: General polynomial

Let  $x_1, x_2, \dots, x_n$  be indeterminates over a field  $F$ . The general polynomial over  $K$  with respect to these indeterminates is

$$(x - x_1)(x - x_2) \cdots (x - x_n)$$

Expand this polynomial, we get  $(x - x_1)(x - x_2) \cdots (x - x_n) = x^n - s_1 x^{n-1} + s_2 x^{n-2} + \cdots + (-1)^n s_n$ . So, each  $s_i$  is an expression of these indeterminates. Then, consider the field by joining  $s_1, \dots, s_n, F(s_1, \dots, s_n), F(x_1, x_2, \dots, x_n)$  is the splitting field of  $F(s_1, \dots, s_n)$  (it contains all roots  $x_1, \dots, x_n$ , and  $F(x_1, \dots, x_n)$  is the smallest field generated

by those roots). Hence,  $F(x_1, x_2, \dots, x_n)/F(s_1, s_2, \dots, s_n)$  is **Galois**.

From now on, let's denote  $F(\underline{x}) := F(x_1, \dots, x_n)$  and  $F(\underline{s}) := F(s_1, \dots, s_n)$

**Proposition 4.1:**  $\text{Gal}(F(\underline{x})/F(\underline{s}))$

$$\text{Gal}(F(\underline{x})/F(\underline{s})) = S_n$$

#### 4.1.2 More on symmetric polynomials

**Project:** Write symmetric polynomials into elementary symmetric polynomials:  
Newton's formula for symmetric polynomials:

[Mos19]

#### 4.1.3 Discriminant and $A_n$

### 4.2 Compute the Galois groups over polynomials

Given any polynomial  $f(x) \in \mathbb{F}_p[x]$ , we want to find  $\text{Gal}(f(x))$ . Let  $\mathbb{K}$  be the splitting field of  $f(x)$  over  $\mathbb{F}_p$ . !!  
 $\mathbb{K}/\mathbb{F}_p$  is a finite extension. From !!,  $\mathbb{K} = \mathbb{F}_{p^k}$  for some  $k$ . So,  $\text{Gal}(f(x)) = \text{Gal}(\mathbb{F}_{p^k}/\mathbb{F}_p) = \langle p \rangle$ .

More precisely, write  $f(x) = \prod_i f_i(x)$  into some irreducible polynomials. The Galois group will be a cyclic group of order  $i(\deg f_i)$ .

What is the relation between this  $k$  and  $n := \deg f(x)$ ? Actually, they are not relevant.  $k$  could be greater than, less than or equal to  $n$ . Here we give three examples:

- (1) For an irreducible polynomial  $f(x)$ ,  $k = n$ . Consider  $f(x) = x^2 + x + 1 \in \mathbb{F}_2[x]$ .
- (2) Consider  $f(x) = x(x - 1) \in \mathbb{F}_3[x]$ . The roots 0, 1 are in  $\mathbb{F}_3$ . So,  $\mathbb{F}_3(0, 1) = \mathbb{F}_3$  and  $\text{Gal}(f(x)) = \{\text{id}\}$ . In this case,  $k = 1 < n = 2$ .
- (3) Consider  $f(x) = g(x)h(x)$ , where  $g(x) = x^2 + x + 1$  and  $h(x) = x^3 + x + 1$ .  $g(x), f(x)$  are irreducible over  $\mathbb{F}_2$ . So, the roots  $g(x)$  are in  $\mathbb{F}_{2^2}$  and the roots of  $h(x)$  are in  $\mathbb{F}_{2^3}$ .  $k = (2, 3) = 6 > n = 5$ .

### 4.3 Inverse Galois problem

## 5 Application to radical solutions of polynomials

Galois theory is developed to answer the question: Does any quintic polynomial (over  $\mathbb{Q}$ ) have a solution formula in radicals? The answer is no. To rephrase 'radicals', we formulate this by introducing 'radical extensions' and prolong a chain of field extension till it enclose the solution. To be more straight-forward, this process is for example, given  $\alpha := \frac{\sqrt{3+\sqrt{5}}}{2}$  and starting from  $\mathbb{Q}$ . First adding  $\sqrt{5}$  into  $\mathbb{Q}$  to get  $\mathbb{Q}(\sqrt{5})$ . But,  $\alpha \notin \mathbb{Q}(\sqrt{5})$ . ??. Then, these field extensions are so special that they are Galois. So, they have connection with their Galois group.

### 5.1 Solvable and radical extensions

### 5.2 The main theorem

**Theorem 5.1: (Abel, Galois)**

Let  $F$  be a field of  $\text{char } K = 0$ ,  $f(x) \in F[x]$  and  $K$  be a splitting field of  $F$  with respect to  $f(x)$ .

$\exists$  a finite extension  $K'/K$  having a root tower over  $F \Leftrightarrow \text{Gal}(K'/F)$  is solvable

#### Proof:

**Lemma 5.1 (Condition for irreducibility)** *Let  $F$  be a field of any characteristic and  $p$  be a prime number. If  $x^p - a \in F[x]$  (or  $a \in F$ ) has no solution in  $F$ , then  $x^p - a$  is irreducible over  $F$ .*

*proof of lemma:* (1) First assume that  $\text{char } F \neq p$ .

(2) Then assume that  $\text{char } F = p$  ♣
